PRELIMINARY IM WORKSHOP FEEDBACK

TransitIQ – GPS-Based Public Transportation Analytics & Management System | BSIT 3B

Preliminary Workshop Score: 76/100

Suggested Improvements by Section

I. Introduction: Please identify the actual organization or operating setting for TransitIQ and narrow the goals to what your current prototype can demonstrate. Mas magiging focused ang framework if the stakeholders and project boundaries are clearly established.

II. Organizational Profile and Information Environment: Clarify which modules and data are already present in your CRUD-based system versus those still proposed (GPS devices, passenger counts, fare transactions and analytics). Ipakita rin the real source and owner of each major dataset.

III. Information Architecture: Connect the three-tier diagram to the actual database: specify your chosen backend and DBMS, main tables, primary identifiers, and the flow from GPS submission to stored trips and reports. Currently, PHP/Node.js, Express/Java and MySQL/PostgreSQL are presented as alternatives without a confirmed design.

IV. MDM Framework: Revisit the Hybrid MDM selection. Edge validation of GPS telemetry alone does not establish Hybrid MDM, because telemetry is operational data rather than master data. Kung iisa ang authoritative database for drivers, routes and vehicles, explain why Centralized / Transactional MDM would not be more appropriate.

V. Data Governance and Quality Policy: Assign concrete accountability for approving route changes, correcting driver/vehicle records, and handling disputed GPS data. Also make the proposed sub-meter accuracy and under-two-second latency measurable targets rather than guaranteed data-quality outcomes.

VI. Privacy, Regulatory, and Compliance Considerations: Distinguish proposed controls from controls already implemented. Clarify whose locations are tracked, who can access trip histories, how long identifiable records remain, and why the 30-day retention period was selected. Iwasan muna ang claim of full RA 10173 compliance without evidence.

VII. Information Security and Risk Management: Make the security strategies from your earlier workshop more concrete by mapping each priority risk to the actual TransitIQ module and a feasible control. For example, explain how spoofed GPS submissions will be checked; input validation alone cannot establish genuine physical location.

VIII. Integration and Use for Decision-Making: Extend the integration matrix to show how verified driver, vehicle, route and GPS records become specific outputs such as fleet-utilization or bottleneck reports. Ipakita the input tables, processing and decision supported—not just projected improvements.

IX. Summary, References and Appendices: Prioritize the next development steps and qualify strong claims such as reduced wait times, accurate arrival predictions and complete legal compliance as expected benefits. Verify the cited sources and ensure risk classifications, diagrams and narrative descriptions are consistent.

Overall Recommendation

TransitIQ has a relevant use case and useful conceptual diagrams, RACI and risk/integration matrices. For the next draft, unahin ang three priorities: (1) confirm the actual CRUD/DBMS structure, (2) align the MDM model

with the architecture, and (3) ground GPS, security, privacy and analytics claims in achievable, clearly labeled controls. AI features are optional and not part of this score.

Preliminary Rubric Summary

Criterion	Maximum	Score
Clarity and Completeness of Framework	25	19
Data Architecture & Technical Integration	20	15
Governance & Privacy Compliance	20	15
Practicality & Innovation	15	11
Report Quality & Presentation	10	9
Documentation & Referencing	10	7
TOTAL	100	76

Assessment note: Score is based on the submitted preliminary manuscript, not independently verified system functionality or attendance. AI integration is optional and ungraded.
